

# Finding and Downloading GIS Data for (mostly) the United States

Instructor: Michael Treglia

Landscape Analysis and Modeling, The University of Tulsa, Spring 2015

\*Note: This material is also available online at [https://github.com/mltConsEcol/TU\\_LandscapeAnalysis\\_Documents/blob/master/Assignments/AccessingGISData.md](https://github.com/mltConsEcol/TU_LandscapeAnalysis_Documents/blob/master/Assignments/AccessingGISData.md)

## Accessing Ecologically-relevant GIS Datasets

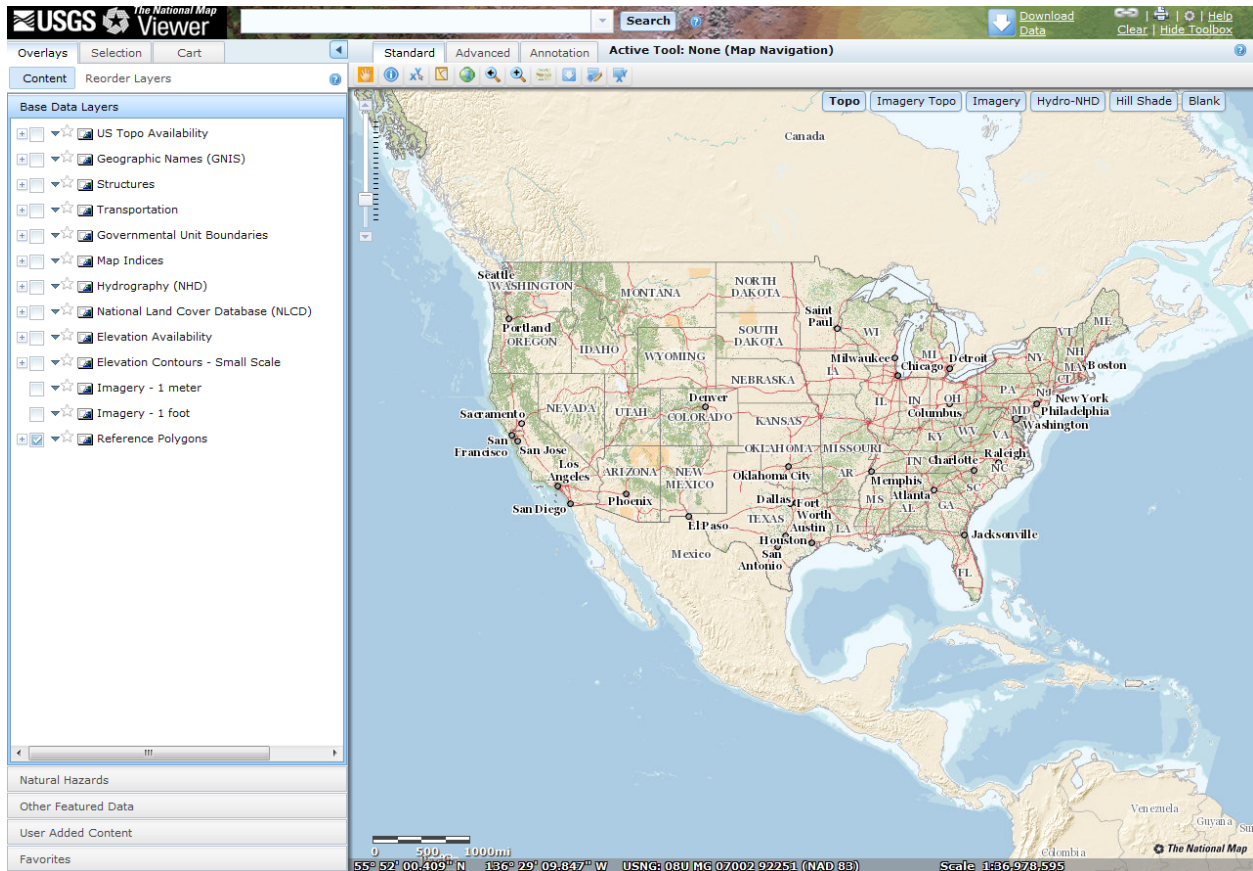

Though many studies use various spatial/GIS datasets, finding and working with them can be a bit of a mystery to a GIS newcomer. This document is designed to point users in the right direction to get started, with a focus on the United States (though some datasets discussed here are also available for other parts of the world). The resources listed below are not necessarily mutually-exclusive to one-another (i.e, you can often find some of the same datasets at multiple places), though some datasets may only be available from individual sources. Detailed instructions on downloading the data are given for the first source to familiarize users with data downloads, but they should explore the other websites to try and figure out how to access the data there - unfortunately every website is a bit different. Typically the projection information is provided and will be read by your GIS software, but if it is not, you may need to look into metadata that comes with the files. This document is meant to get users started, and is thus not to serve as a comprehensive manual for accessing every data source available. Remember - Google is your friend. If it helps, start at these websites to look for datasets you need; if you can't find them, they may exist, but that might require some web-searches. Also, internet Q&A outlets like [GIS Stack Exchange](#) are invaluable when you really get stuck.

## National-Scale Data

### The National Map

[The National Map](#) is kind of a one-stop-shopping location for lots of datasets that are distributed by the U.S. Government. These include vector layers of political boundaries, hydrologic data including stream networks and watershed boundaries from the [National Hydrography Dataset](#), and roads. These layers are typically available for download as shapefiles or geodatabase files. Raster datasets that are available include elevation (digital elevation models [DEMs]) from the [National Elevation Dataset](#), land cover classifications from the [National Land Cover Database](#), and aerial imagery.

To view what is available and download available datasets, use [The National Map Viewer](#) platform. Upon opening the webpage, you will see something similar to the image below. Browse this page - hover your mouse over the icons just above the the map to see what they do, and expand the lists of layers on the left by clicking the + and - icons next to the categories. Check and un-check the boxes to see what these data look like; use the scroll-wheel on your mouse, or the magnifying glass with the + in it to adjust the zoom. You can also search for specific places in the search bar at the top. Note, for the layers labeled “... Availability”, this will show polygons representing areas that the data are available for, as the layers themselves can be complex. However, when you go to download data, you will be able to download the actual layers.

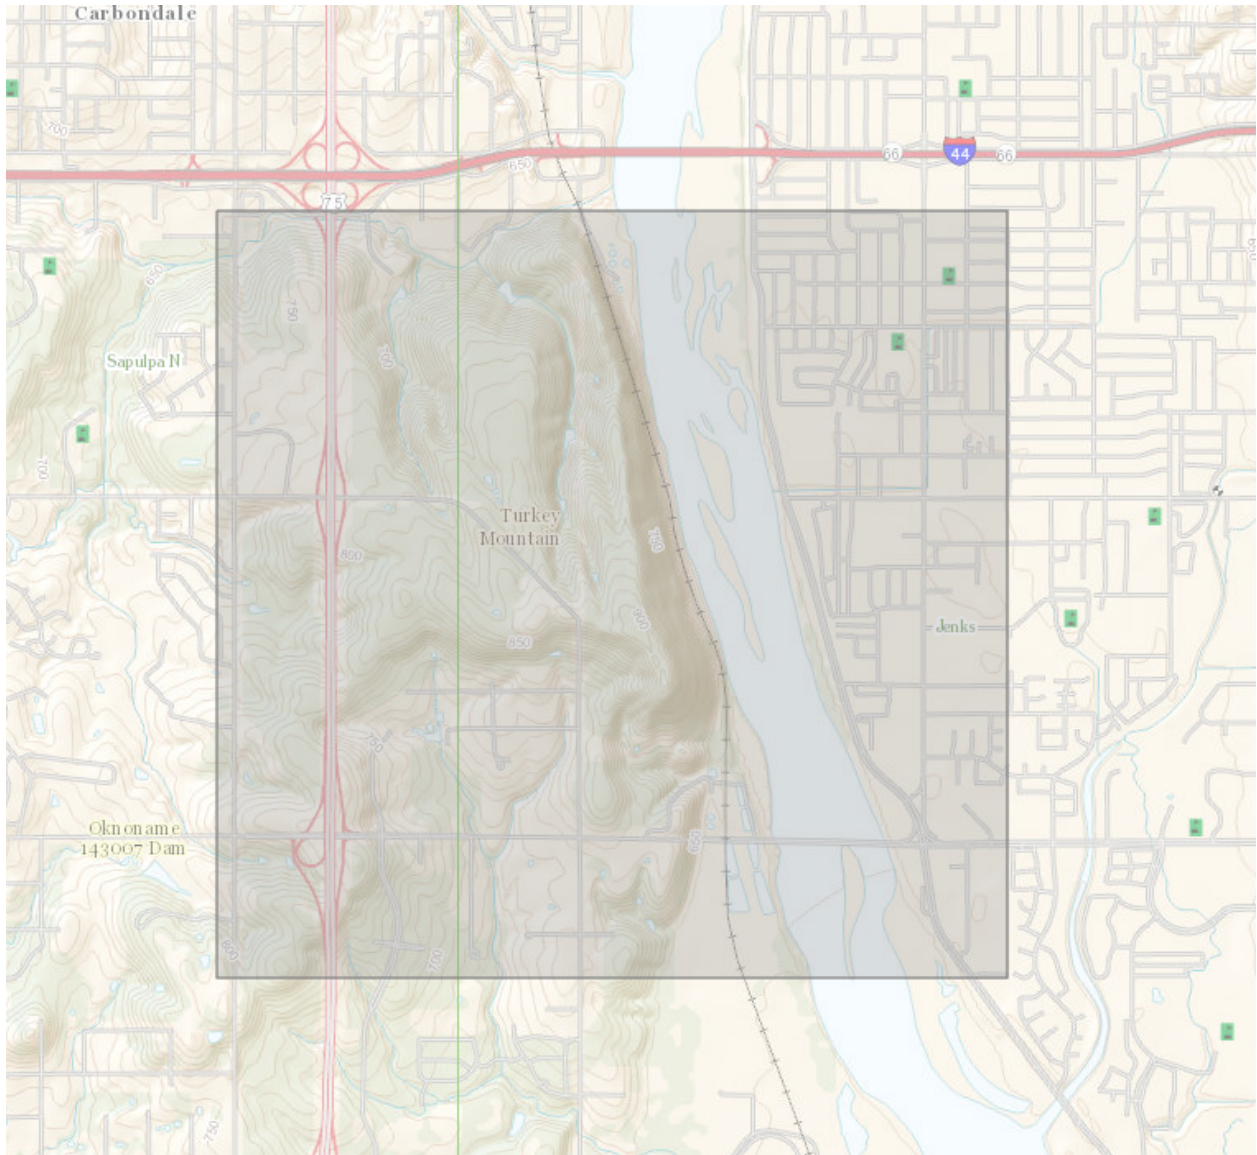

**Downloading Data from The National Map**  To begin the process of downloading data from The National Map, simply click one of the “Download Data” icons, either at the top of the webpage, or just above the map window (in a row with other icons). You do not need to have the layers you want to download visible on your map; you will select the layers in a later step.

You can select any of the appropriate options for defining the extent of data you wish to download. For beginners to GIS, the simplest ways are likely:

- draw and download by bounding box;
- download by current map extent; or

- download by coordinate input.

In this example, we'll focus on a natural area near our campus, Turkey Mountain. A search for "Turkey Mountain, Tulsa, OK" yields a fairly accurate result. Zoom to the appropriate area, and select the option to download data by drawing a bounding box (the first option). Here's an image of the bounding box I have selected:

After you draw the box, a new window will appear with check-boxes of data you want to download. For now, let's check the options for "Boundaries" and "Elevation" and click "Next" (read the on-page instructions at this point if you are having issues).

A new window should now appear (image below), with lots of products available to download (right now you are only looking at the "Boundaries" products; you'll need to click the gray "Elevation" category to access those). Admittedly, this can be a bit overwhelming, and it might take a bit of trial and error to figure out what you need. In most contexts, for vector data, shapefiles are the easiest to work with, but you might need to download a "File GDB" option instead. In this case, the third

option, “USGS National Boundary Dataset (NBD) for Oklahoma 20140401 State or Territory Shapefile” might suffice, but if you want the fine-scale map of cities and towns, scroll down to that option as well. Check the box for both of those. If data are available for multiple dates, but they otherwise look the same, get the most recent, or most appropriate for your focal time period.

#### USGS Available Data for download x

Use the **checkboxes** to select specific format of products you want under each theme. Click on the products to preview their footprints on the map. Products will be added to the Cart on the left side of the screen.

Boundaries (10 products)				
<input type="checkbox"/>	Product	Date	Format	Info
<input type="checkbox"/>	USGS National Boundary Dataset (NBD) for Oklahoma 20140401 State or Territory FileGDB 9.3.1	4/1/2014	File GDB 9.3.1	
<input type="checkbox"/>	USGS National Boundary Dataset (NBD) for Oklahoma 20140401 State or Territory FileGDB 10.1	4/1/2014	File GDB 10.1	
<input type="checkbox"/>	USGS National Boundary Dataset (NBD) for Oklahoma 20140401 State or Territory Shapefile	4/1/2014	Shapefile	
<input type="checkbox"/>	USGS Small-scale Dataset - Indian Lands of the United States 200606 Shapefile	6/1/2006	Shapefile	
<input type="checkbox"/>	USGS National Boundary Dataset (NBD) for Texas 20140401 State or Territory FileGDB 9.3.1	4/1/2014	File GDB 9.3.1	
<input type="checkbox"/>	USGS National Boundary Dataset (NBD) for Texas 20140401 State or Territory FileGDB 10.1	4/1/2014	File GDB 10.1	
<input type="checkbox"/>	USGS National Boundary Dataset (NBD) for Texas 20140401 State or Territory Shapefile	4/1/2014	Shapefile	
Elevation (24 products)				

Back

Next

Next, open the tab for “Elevation” - again, there are lots of options. Notice that in the product name, it typically says “1 arc-second”, “1/3 arc-second” or “100 [or 200]-Meter Resolution” - this identifies the resolution (i.e., grain size), as these are raster layers. 1 arc-second is ~30 meters x 30 meters and 1/3 arc-second is ~10 meters x 10 meters. You’ll notice there are also a number of formats available. GeoTIFF or IMG files are typically among the easiest to open, with the projection information embedded and nothing to do but import those in QGIS. If you are working with a large area, you’ll have to take notice of the location these are from - in the name, the n37w096 indicates the latitude/longitude of the upper left corner of the individual tile. For large areas, it will have multiple tiles with different latitude/longitude designations, and you’ll need to download all that cover your study area. In this case, we’ll select the “USGS NED n37w096 1 arc-second 2013 1 x 1 degree IMG”.

After you select all desired layers, click the “Next” button. (In your own work, select whatever layers you might need.)

On the left hand side of the screen, a new panel should be displayed, the “Cart” - you can click on the

products you previously selected, and a preview will appear; you can also remove layers, or opt to add more. If you are satisfied with the selection, click “Checkout” to move on with your data order. You’ll need to enter your e-mail address twice, and click the “Place Order” button. You’ll receive download links in your e-mail, though it can take a little while. The links typically don’t work in Mozilla Firefox, but work to start downloads in Internet Explorer or Google Chrome.

Once you have the data downloaded, you can import them into your favorite GIS software.

## USDA GIS Resources

The [USDA Geospatial Gateway](#) also has a wide variety of data available for download, including soil data, and high resolution aerial imagery. To get started, go to the [website](#) and click the green “Get Data” button (towards the upper-right).

From there, you’ll need to select the desired State/County of interest, and the datasets you need. see the panes on the left of the screen that describe each step, as in the example below). Note, this website has available Climate data from PRISM, further described below.

USDA United States Department of Agriculture  
Natural Resources Conservation Service

**1-WHERE**  
**2-WHAT**

The list in the middle pane indicates the available map layers for your area of interest. The number of maps and total size of the map layers are listed next to the description. Clicking on the icon will provide a pop-up window with that map layer's description. Use the icon to get a list of individual maps for that map layer. Within the list of maps, use the icon to get metadata for the specific map and the icon for an individual map preview. You may collapse this map list with the icon. Your selections will be added to the YOUR ORDER Panel on the far right.

You may change your map layers after this step but all of the subsequent choices made for your order will be removed.

Maps in layers that are "...by State" cover an entire state.

**3-HOW**  
**4-WHO**  
**5-REVIEW**

**WHAT**

Here are the available map layers for your selected area of interest.

**Cadastral**

- ☐ Public Land Survey System (PLSS) Townships, 1 map 0.050 MB
- ☐ Public Land Survey System (PLSS) Sections, 1 map 0.406 MB

**Census**

- ☐ TIGER 2010 Census Blocks, 1 map 2.994 MB
- ☐ TIGER 2010 Census Block Groups, 1 map 0.204 MB
- ☐ TIGER 2010 Census Tracts, 1 map 0.097 MB
- ☐ TIGER 2010 State and County Demographic Statistics by State, 1 map 1.088 MB
- ☐ TIGER 2010 County Social, Economic, Housing Stats by State, 1 map 2.775 MB

**Climate Precipitation**

- ☐ 1961-1990 Monthly Average Precipitation by State, 12 maps 2.610 MB
- ☐ 1961-1990 Annual Average Precipitation by State, 1 map 0.206 MB
- ☐ 1971-2000 Monthly Average Precipitation by State, 12 maps 3.509 MB
- ☐ 1971-2000 Annual Average Precipitation by State, 1 map 0.630 MB
- ☐ 1981-2010 Monthly Average Precipitation by State, 12 maps 5.112 MB
- ☐ 1981-2010 Annual Average Precipitation by State, 1 map 2.129 MB

**Climate PrismRaster**

- ☐ 1961-1990 Annual Average Raster Precipitation by State, 1 map 0.693 MB
- ☐ 1971-2000 Annual Average Raster Precip and Temp by State, 1 map 18.826 MB
- ☐ 1981-2010 Annual Average Raster Precip and Temp by State, 1 map 11.297 MB

**Climate Temperature**

- ☐ 1971-2000 Annual Average Minimum Temperature by State, 1 map 2.399 MB

## State GIS Resources (for Oklahoma)

Most states have their own repositories for GIS data. Typically when I'm trying to find such a repository, I do a Google search for something along the lines of these phrases: "[Insert State Name] GIS Data"; "[Insert State Name] GIS Repository"; "[Insert State Name] GIS Warehouse"; or "[Insert State Name] GIS Clearinghouse". Here are also a couple of websites that list some resources available by state:

- [Tulsa City-County Library GIS resources](#)
- [Carleton College webpage from the National Association of Geoscience Teachers](#)

For Oklahoma, a couple of particular websites that can be useful are:

- [The OKMaps Website](#)
- [Center for Spatial Analysis at the University of Oklahoma](#)

## Climate Data

Climate data are typically recorded at individual weather stations, though in ecological studies, it is typically useful to have summaries of climate conditions for entire landscapes, describing characteristics of temperature and precipitation regimes. Thus, multiple organizations have interpolated the data from weather stations, to estimate conditions for large areas. There are two main sources I frequently go to, listed below. Browse the respective website for information on downloading the data. If you need information from a specific weather station, you can search the resources from the [NOAA National Climatic Data Center](#). Other sources may be available from state-wide monitoring networks (e.g., [Mesonet for Oklahoma](#) and other organizations).

- [PRISM Climate Group at Oregon State](#)
  - Has 800 meter pixel data for the continental United States
  - Lots of information, including 30 year normals for monthly and annual precipitation, maximum temperature, and minimum temperature.
  - Also has elevation layers, historical data, and recent data for individual months
- [WorldClim Global Climate Data](#)
  - Global Dataset of 30 second resolution (~800-1,000 meter resolution); Coarser resolutions are available (which are smaller file size)
  - Monthly and annual minimum, maximum, and mean temperature and precipitation
  - Also contains "Bioclim" layers - described [here](#)
    - \* These layers are derived from monthly precipitation and temperature data, to describe the climate in biologically meaningful ways.
  - Datasets include current conditions (based on 50 year average), projected future conditions under various climate change scenarios, and historical conditions.

## **A Note about Spatial Reference Information for GIS Data Layers**

When you load data into a GIS program, the projection information should automatically be interpreted by the software, if it is stored correctly with the relevant files. If the projection information is non-existent, you may need to look through metadata files that come with the data (often stored in '.xml' or '.html' documents, labelled as 'metadata'). If you find the projection and need to set it in your GIS software, it may be easiest to do so by filtering for specific terms you find in the metadata. Furthermore, an internet search for the information you find in the metadata, with "EPSG" code in the search phrase can help you find a code used in GIS, the EPSG Code. For example, a Google search for 'wgs 84 epsg' returns [this webpage](#) as the first result, and indicates the EPSG code for projected (i.e., global coordinates of lat/long) in the datum WGS 84 is 4326.
